# 

## A. Broader Impact

The key result of this research could aid the GNN family since G-RNA is able to search for robust architectures for learning graphs automatically. The proposed approach can simultaneously enhance the accuracy as well as the resilience to adversarial assaults of GNNs, allowing them to be used in more safety-critical applications including power grids, financial transactions, and transportation.

# **B.** Additional Experimental Results

## **B.1. Defense Performance Against Target Attacks**

Targeted attacks and non-targeted attacks are two vital branches of the adversarial attack field. In this section, we compare our proposed methods to baselines under a targeted attack, Nettack [51], as a complement to defensive results under nontargeted attacks. For each dataset, we choose 40 correctly classified nodes (10 nodes with highest margin, 10 nodes with the lowest margin, and 20 nodes randomly) and report the average classification accuracy for these target nodes. Note that this setting leads to higher reported accuracy than the typical accuracy evaluated on the whole test set. We conduct this experiment for five runs and the defensive performance is shown in Table 4. It reads that G-RNA still outperforms the other baselines almost across all datasets under the perturbed setting, while maintains on par performance on the clean graphs.

Table 4. Defensive performance on targeted nodes (mean in percentages) under targeted attacks Nettack. "-" indicates the result is unavailable due to the high time complexity of the model.

Dataset	Model	GCN	GCN-JK	GAT	GAT-JK	GCN-Jaccard	Pro-GNN	GraphNAS	G-RNA
Cora	No Attack Attack	93.25 16.75	94.75 16.25	94.75 19.25	92.25 23.75	98.50 46.25	97.50 50.00	96.00 25.75	94.95 51.25
Citeseer	No Attack Attack	88.00 14.75	86.25 12.50	91.00 17.25	88.25 14.75	95.25 22.00	92.50 45.00	96.25 9.00	92.50 60.00

# **B.2.** Defense on Heterophily Graph

To better illustrate the effectiveness of our proposed method, we select one heterophily graph, Wisconsin and evaluate the performance of G-RNA on it. Table 5 demonstrates the performance of various methods under both clean and perturbed data, where 5% edges are manipulated by Mettack. We could find that even without the assumption of graph homophily, our method could outperform other baselines under both settings.

Table 5. Experimental result on heterophily graph.

GCN		G	AT	GCN-Jaccard		
clean 50.55±1.69	perturbed 48.95±2.16	clean 52.40±2.22	perturbed 52.1±2.20	clean 53.60±3.32	perturbed 52.15±2.06	
Pro-GNN		GraphNAS		G-RNA		
51.05±0.58	48.2±1.99	58.10±4.70	57.60±2.80	60.50±2.97	59.25±2.76	

### **B.3.** Details of Searched Architectures

The optimal searched architectures by G-RNA for each dataset are listed in Table 6. The optimal model depth searched is 2-layer for Cora and CiteSeer, and 3-layer for PubMed. All three architectures use NFS as the pre-processing adjacency mask.

*NIE* is selected in the second layer for CiteSeer and Cora. Besides, *LSTM* is chosen to be the layer aggregator for Cora and PubMed, while *Concat* is selected for CiteSeer.

Table 6. Searched architectures results.

Dataset	Layer Intra-layer Operations		Layer aggregator
Cora	layer1: <i>Skip</i> layer2: <i>Skip</i>	[NFS, GAT-Cos, Sum, Identity] [Identity, Identity, Sum, Identity]	LSTM
CiteSeer	layer1: None layer2: Skip	[NFS, Identity, Mean, SAGE] [NIE, GAT-Cos, Mean, SAGE]	Concat
PubMed	layer1: <i>Skip</i> layer2: <i>None</i> layer3: <i>Skip</i>	[NFS, Identity, Mean, SAGE] [NIE, Identity, Sum, GIN] [Identity, GAT-Sym, Mean, Identity]	LSTM
ogbn-arxiv	layer1: Skip layer2: Skip	[NFS, gat, Sum, GIN] [Identity, GAT-Sym, Sum, GIN]	Concat
$Amazon_{photo}$	layer1: <i>Skip</i> layer2: <i>Skip</i> layer3: <i>Skip</i>	[NFS, GAT-Linear, Sum, GIN] [Identity, Identity, Sum, GIN] [Identity, GAT-Sym, Sum, Identity]	Concat

## **B.4. Sensitivity Analysis**

To in-depth understand the effect of the hyper-parameter  $\lambda$  in the search process, we conduct an ablation study on sensitivity of it. Figure 5 shows the performance for  $\lambda=0.01,0.05,0.5$  on Cora dataset. The experiments on the other datasets show similar patterns. When  $\lambda$  is very small, e.g., 0.01, the performance on clean data is gratifying, but the performance drops fast under adversarial perturbations. On the contrary, when  $\lambda$  is relatively large, e.g., 0.5, the prediction accuracy on clean graph is poor, but the performance is stable even when the graph is heavily attacked. As a result, we need to properly balance the accuracy and robustness tradeoff by choosing a suitable  $\lambda$ . In practice, we find that tuning  $\lambda$  in the range of [0.05,0.3] usually leads to satisfactory results.

Table 7. Recover existing GNN layers from our search space.

Method	$\ \ \left  \ \left[ \mathcal{O}_{\mathcal{D}}, \mathcal{O}_{e}, \mathcal{O}_{aggr}, \mathcal{O}_{comb}, \mathcal{O}_{skip} \right] \right.$
GCN [22]	[Identity, GCN, Sum, Identity, None]
JK-Net [42]	[Identity, GCN, Sum, Identity, Skip]
GAT [35]	[Identity, GAT, Sum, Identity, None]
GIN [41]	[Identity, Identity, Sum, GIN, None]
GraphSAGE [15]	[Identity, Identity, Mean, SAGE, None]
GNN-Guard [44]	[NIE, GCN, Sum, Identity, None]
VPN [20]	[VPO, GCN, Sum, Identity, None]

Table 8. Commonly used correlation coefficient operations.

$\mathcal{O}_e$	Formula
Identity	$\left \begin{array}{l}e_{ij}^{iden}=1\end{array}\right.$
GCN	$\mid e_{ij}^{gcn} = 1/\sqrt{d_i d_j}$
GAT	$\left \begin{array}{c} e_{ij}^{gat} = leaky\_relu(\mathbf{W}_l\mathbf{h}_i + \mathbf{W}_r\mathbf{h}_j) \end{array}\right $
GAT-Sym	$\left  \begin{array}{c} e^{sym}_{ij} = e^{gat}_{ij} + e^{gat}_{ji} \end{array} \right.$
Cos	$\mid e_{ij}^{cos} = <\mathbf{W}_l\mathbf{h}_i, \mathbf{W}_r\mathbf{h}_j>$
Linear	$\left \begin{array}{l}e_{ij}^{lin}=tanh(sum(\mathbf{W}_{l}\mathbf{h}_{i}))\end{array}\right.$
Gene-Linear	$\left  \begin{array}{l} e_{ij}^{gene} = \mathbf{W}_a tanh(\mathbf{W}_l \mathbf{h}_i + \mathbf{W}_r \mathbf{h}_j) \end{array} \right $

# **B.5.** Computational Efficiency Analysis

We also empirically demonstrate the computational efficiency of G-RNA in comparison with two comprehensive baselines, GraphNAS and Pro-GNN, on Cora dataset in Table 9. Due to the usage of graph structure mask operations and the evolutionary algorithm, our methods are not that efficient like darts-based NAS methods or plain robust GNN solution. However, we can find that the computation cost of our G-RNA is comparable to GraphNAS. This lack of efficiency is consistent with one

of the limitations that we claimed in Section 6, which is a shared issue for many NAS methods and we choose to leave its improvement as a future work.

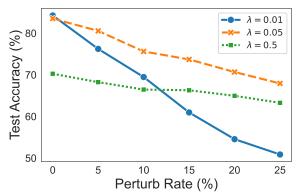

Table 9. Running time (hours) comparison on Cora dataset.

Pro-GNN	GraphNAS	G-RNA
0.22	4.12	2.23

Figure 5. Parameter sensitivity analysis for  $\lambda$ .

#### C. Details of G-RNA

## C.1. Examples of popular GNNs based on search space of G-RNA

Our search space could recover some classic and manually designed GNNs as well as state-of-the-art robust GNNs such as GCN-SVD, GCN-Jaccard, GNN-Guard, and VPN.

## C.2. Evolutionary search algorithm

Based on our proposed robustness metric, we adopt the evolutionary algorithm to search for the optimal robust architectures, as shown in Algorithm 1. Inspired by biological evolution process, the evolutionary algorithm solves optimization problems by mutation, crossover, and selection. The selection operation is conducted via a fitness function, which is set as  $ACC_{val}(\alpha) + \lambda R(\alpha)$  in our algorithm. The inference function in Line 3 calculates the fitness score from the validation set.

#### **Algorithm 1:** Evolutionary Search Algorithm

**Input:** The maximum iteration number  $max\_iter$ , supernet weights  $\mathbf{W}$ , the population size P, the mutation size s, the mutation probability p, the crossover size n, the original graph  $G = (\mathbf{A}, \mathbf{X})$ , the perturbed adjacency matrices  $\{\mathbf{A}'_t, i = t, ..., T\}$ , the number of optimal architectures k.

**Output:** The top-K architectures with the highest robustness metric.

```
1 candidates \leftarrow initialize\_population(P);

2 for iter = 1, ..., max\_iter do

3 | Q \leftarrow Inference(candidates, G, \{A'_i\});

4 | Top-k \leftarrow Select\_top(Q, candidates, k);

5 | P_{crossover} \leftarrow Crossover(Top-k, n);

6 | P_{mutation} \leftarrow Mutation(Top-k, s, p);

7 | candidates \leftarrow P_{crossover} \cup P_{mutation};

8 Return Top-k
```

### C.3. Correlation coefficient operations

For correlation coefficient operations, we follow the literature and the detailed formulas are given in Table 8.

# **D.** Experimental Setup

In this section, we start with the dataset statistics then describe the implementing details for G-RNA and other baselines.

#### D.1. Dataset

We mainly consider the semi-supervised node classification task on three citation graph datasets [33], including Cora, CiteSeer, and PubMed. For each graph, we randomly select 10% nodes for training, 10% nodes for validation, and the rest 80% nodes for testing to be consistent with existing literature. Besides, we also evaluate the effectiveness of G-RNA on one heterophily graph, one citation network from Open Graph Benchmark (OGB) [17] and a co-purchase network that intends to predict the product category on Amazon [31]. The specific statistics for each dataset are shown in Table 10.

Table 10. Dataset statistics.

Dataset	# Nodes	# Edges	# Features	# Classes
Cora	2,708	5,429	1,433	7
Citeseer	3,327	4,732	3,703	6
PubMed	19,717	44,338	500	3
ogbn-arxiv	50,802	108,554	128	40
Amazon-photo	7,650	119,081	745	8
Winsconsin	251	499	1703	5

#### D.2. Baselines

In order to validate the effectiveness and robustness of our G-RNA, we compare it with state-of-the-art GNNs, manuallydesigned robust GNNs, and Graph NAS methods:

- GCN [22]: Graph Convolution Network (GCN) is the pioneer of GNN and represents as a classic victim model against adversarial attacks.
- GCN-JK [42]: GCN-JK combines GCN with jumping knowledge networks (JK-Net). JK-Net adds skip connections among different hidden layers and adaptively learns node-wise neighborhood when aggregating node representations.
- GAT [35]: Graph Attention Network (GAT) utilizes self-attention mechanism to learn different weights for edges.
- GAT-JK [42]: GAT-JK is the combination of GAT and JK-Net. Again, We use GNNs and their JK-Net variants to study the effect of JK-Net backbone.
- RGCN [49]: Robust Graph Convolutional Network (RGCN) is an attention-based defense model by treating node representations as Gaussian distribution and assigning less attention to nodes with high variance.
- GCN-Jaccard [39]: GCN-Jaccard conducts edge pruning according to the jaccard similarity among node representations. It is a simple yet effective pre-processing defensive baseline.
- Pro-GNN [21]: Based on the graph properties of sparsity, low rank, and feature smoothness, Property GNN (Pro-GNN) learns parameters and purifies the adjacency matrix at the same time.
- GraphNAS<sup>2</sup> [10]: GraphNAS serves as a baseline that validates the robustness of plain graph NAS under adversarial attacks.

Except GraphNAS, we use the public implementation for all baselines via PyTorch Geometric (PyG) [9] and DeepRobust [25].

## **D.3. Parameter Settings**

To search for the optimal robust GNNs, we firstly construct a supernet and train it afterwards. Then, we search with our robustness metric using the weights of the trained supernet. At last, we retrain the top-3 selected architectures from scratch. For the construction of supernet, we limit the maximum layer number as 3.

Since random attack is one simple yet effective attack method, we use random attack as our attack proxy and generate 10 perturbed graph (T=5) with 5% perturbation rate. Meanwhile, it is easy to implement, so that we use it to evaluate the

<sup>&</sup>lt;sup>1</sup>https://github.com/kimiyoung/planetoid/tree/master/data

<sup>&</sup>lt;sup>2</sup>https://github.com/GraphNAS/GraphNAS

robustness of architectures without the knowledge of the specific attacker. Some other attack algorithms could also be ultilized to generate adversarial examples for the evaluation of robustness metric if some prior knowledge from the attacker is given.

For the proposed G-RNA, the supernet is trained for 1,000 epochs with a learning rate of 0.005 and a weight decay of 3e-4. The linear dropout rate is fixed to 0.5, and the attention dropout rate is fixed to 0.6.  $\lambda$  is determined through grid-search and selected as 0.05 for Cora, 0.25 for CiteSeer, and 0.2 for PubMed. For robust operations, the reconstruction rank for LRA is set to 20, and the threshold for NFS operation is chosen as 0.01. We maintain the power order of VPO to be 2 for all datasets. In the generic search algorithm, we set population size P=50, mutation size s=20, mutation probability s=0.2, crossover size s=20, and optimal architecture number s=10. After we finish the search, we continue to tune the hyper-parameters using hyperopt with the following options to gain the best results:

- hidden size: {16, 32, 64, 128, 256}
- learning rate: {0.005, 0.01}
- weight decay: {5e-3, 1e-3, 5e-4, 1e-4}
- optimizer: {adam, adagrad}
- linear dropout: {0, 0.3, 0.5, 0.7}
- attention dropout: {0.5, 0.6, 0.7}

For all models, we train them on ogbn-arxiv for 500 epochs and on all the other datasets for 200 epochs. For vanilla GNNs, we set the learning rate as 0.005 using the Adam optimizer. Other hyper-parameters are kept the same as the original papers. For GNN-Jaccard, we tune the threshold for jaccard similarly from {0.01,0.02,0.03,0.04,0.05}. For RGCN, the hidden size is tuned from {16, 32, 64, 128}. For Pro-GNN, we follow the original settings to fix the hidden size as 64 for Cora and CiteSeer. The results of Pro-GNN for PubMed dataset is not available due to its high time complexity. For GraphNAS, we keep the same setting as reported in the original paper. We ran all experiments on a single machine with a 16GB GeForce GTX TITAN X GPU.
